CHAPTER 2

DARK MATTER IN THE COSMOS

2.1 Introduction

I'll attempt to explain the dark matter problem at an entry level with the following thought experiment. Let's say you're the teacher for an elementary school classroom. You take them on a field trip to your local science museum and among exhibits is one for mass and weight. The exhibit has a gigantic scale, and you come up with a fun problem for your classroom.

You say to your class, "What is the total weight of the classroom? Give your best estimation to me in 30 minutes, and then we'll check on the scale. If your guess is within 10% of the right answer, we will stop for ice cream on the way back"

The students are ecstatic to hear this, and they get to work. The solution is some variation of the following strategy. The students should give each other their weight or best guess if they don't know. Then, all they have to do is add each students' weight and get a grand total for the class. The measurement on the giant scale should show the true weight of the class. When comparing the measured weight, multiply the observation by 1.1 and 0.9 in order to get the +/- 10% tolerance respectively.

Two of your students, Sandra and Mario, return to you with a solution.

They say, "We weren't sure of everyone's weight. We used 65 lbs for the people we didn't know and added everyone who does know. There are 30 of us, and we got 2,000 lbs! That's a ton!"

You estimated 1,900 lbs assuming the average weight of a student in your class was 60 lbs. So you're pleased with Sandra's and Mario's answer. You instruct your students to all gather on the giant scale and read off the weight together. To all of your surprise, the scale reads *10,000 lbs!* 10,000 is significantly more than a 10% error from 2,000. In fact, it is approximately 5 times more massive than either your or your students' estimates. You think to yourself and conclude there must be something wrong with the scale. You ask an employee to check the scale and verify it is calibrated well. They confirm that the scale is in working order. You weigh a couple of students individually to test that the scale is well calibrated. Sandra weighs 59 lbs, and Mario weighs 62 lbs,

typical weights for their age. You then weigh each student individually and see that their weights individually do not deviate greatly from 60 lbs. So, where does all the extra weight come from?

This thought experiment serves as an analogy to the Dark Matter problem. The important substitution to make however is to replace the students with stars and classroom with a galaxy, say the Milky Way. Individually the mass of stars is well measured and defined with the Sun as our nearest test case. However, when we set out to measure the mass of a collection of stars as large as galaxies, our well motivated estimation is wildly incorrect. There simply is not way to account for this discrepancy except without some unseen, or dark, contribution to mass and matter in galaxies. I set out in my thesis to narrow the possibilities of what this Dark Matter could be.

This chapter is organized like the following. . . **TODO: Text should look like ... Chapter x has blah blah blah.**

2.2 Dark Matter Basics

Presently, the most compelling Dark Matter (DM) model is Λ Cold Dark Matter, or Λ CDM. I present the evidence supporting Λ CDM in 2.3, yet discuss the conclusions of the Λ CDM model here. According to Λ CDM fit to observations on the Cosmic Microwave Background (CMB), DM is 26.8% of the universe's current energy budget Baryonic matter, stuff like atoms, gas, and stars, contributes to 4.9% of the universe's current energy budget [1–3].

DM is dark; it doesn't interact readily with light at any wavelength. DM also doesn't interact noticeably with the other standard model forces (Strong and Weak) at a rate that is readily observed [3]. DM is cold, which is to say that the average velocity of DM is below relativistic speeds [1]. 'Hot' DM would not likely manifest the dense structures we observe like galaxies, and instead would produce much more diffuse galaxies than what is observed [1, 3]. DM is old; it played a critical role in the formation of the universe and the structures within it [1, 2].

Observations of DM has so far been only gravitational. The parameter space available to what DM could be therefore is very broad. Searches for DM are summarized by supposing a hypothesis that has not yet been ruled out, and performing measurements to test them. When the observations yield a null result, the parameter space is further constrained. I present some approaches for DM

122 searches in Section 2.4.

123 **2.3 Evidence for Dark Matter**

124 Dark Matter (DM) has been a looming problem in physics for almost 100 years. Anomalies
125 have been observed in galactic dynamics as early as 1933 when Fritz Zwicky noticed unusually
126 large velocity dispersions in the Coma cluster. Zwicky's measurement was the first recorded to
127 use the Virial theorem to measure the mass fraction of visible and invisible matter in celestial
128 bodies [4]. From Zwicky in [5], *"If this would be confirmed, we would get the surprising result*
129 *that dark matter is present in much greater amount than luminous matter."* Zwicky's and other's
130 observation did not instigate a crisis in astrophysics because the measurements did not entirely
131 conflict with their understanding of galaxies [4]. In 1978, Rubin, Ford, and Norbert measured
132 rotation curves for ten spiral galaxies [6]. Rubin et. al.'s 1978 publication presented a major
133 challenge to the conventional understanding of galaxies that could no longer be accredited to
134 measurement uncertainties. Evidence has been mounting ever since for this exotic form of matter.
135 The following subsections sample some of the compelling evidence supporting DM.

136 **2.3.1 First Clues: Stellar Velocities**

137 Ok so someone [FACT CHECK THIS][NEEDS A SOURCE] started taking measurments with
138 at. They were curious about what speed stars were orbitting the galaxies they were contained in.
139 These measurements were done for things close by. At the time we were even that sure galaxies
140 were a thing. Bu with the basical knowlwedge we had we used the virial theorem with the velocities
141 of the stars to measure the mass inderectly of the galaxies.

$$142 \text{ } \textcolor{green}{INSERTTheVirialEqnHERE.} \quad (2.1)$$

142

143 **TODO: explain the virial equation**[NEEDS A SOURCE]you probably want to source the theory
144 behind why this important

145 The verdict wasnt clear however until Vera Rubin made some awesome discoveries with more
146 precise equipment and 21cm lines of Hydrogren gas in the galaxies. This really showed that

147 there was some unexplained discrepancy between how much mass we were seeing in the stars
148 and the mass measured indirectly. The issue is that it we're pretty sure now that we're not just
149 under-estimating the mass of the stars [NEEDS A SOURCE]. The difference in mass was up to 5x
150 which is way way too much for what our uncertainties were (somewhere around 20%)[NEEDS A
151 SOURCE].

Figure 2.1 TODO: velocity dispersion old here.[NEEDS A SOURCE][FACT CHECK THIS]

152 Nowadays we have more measurements of the stellar velocities and have even discovered small
153 DM dense bodies called dwarf spheroidals (dSph) These measurements have been made by the
154 community [FACT CHECK THIS]and there are compiled lists of how much DM these objects
155 have. Most of these measurements are made from newtonian virial theorem measurments. There
156 has since emerged new evidence. These innovative techs are discussed in the following sections.
157 The evidence cullminates into a story of particle dark matter.

2.3.2 Mounting Evidence for Dark Matter

Modern evidence for dark matter comes from new avenues. We got microlensing which supports DM in the general relativity sector. The Cosmic Microwave Background shows that the universe has DM in it from a very early stage. The CMB is the primordial light from the young universe. Basically a baby photo. Then we have computational models where we model the universe. Then we look at how the simulated universes look like compared to what we see. From those simulations we infer how much dark matter is in the universe. The fuller explanations and shortcoming of each of these methods is explained further in this section.

someone took a an observation of the bullet cluster. The microlensing of galaxy clusters are some of the most damning evidence that DM is actually matter and not just a flaw in our gravitational theories. There were two galaxy clusters [FACT CHECK THIS]. They clearly passed through each other at some point in the past and are in the process of merging [NEEDS A SOURCE]. Two observations of the clusters were made independantly of each other. The first was the microlensing of light around the galaxies due to their gravitational influences. When celestial bodies are large enough, the gravity they exert bends space and time itself. This bending effects light and will deflect light in a smilar way to how lenses will bend light.

With a sufficient understanding of light sources behind a celestial body, you can reconstruct the countours of the gravitational lenses. The gradient of the contours then tells you how dense the matter is and where it is.

They then made measurements of the x-ray emmision from the clusters. The idea is that since these galaxies are mostly gass and are merging, then they should be getting hotter. If they're merging, the x-ray emmisions should be the strongest where the gas is mostly moving through each other. The x-rays basically map out where the gas is in these merging galaxies.

The dope super interesting thing is that the map of the x-ray emmisions totally doesnt align with the gravitational countours from the microlensing. This incongruence is really telling that there is a lot of matter somewhere that we jsut cannot see. Moreover this matter is NOT BARYONIC. So then what is it? This measurement didn't really tell us what exactly, but it did suggest that this DM

Figure 2.2 **TODO: gravitational lensing figure compared to glass lensing.**[NEEDS A SOURCE][FACT CHECK THIS]

185 also doesn't interact with itself very strongly. If it did, then it would have been more aligned with
 186 where the x-ray emission was. There's been other studies of galaxies with similar results altho
 187 there are a handful that resemble something we expect for strongly self-interacting DM. [NEEDS
 188 A SOURCE]. This result really makes it hard to argue that DM is somehow something amiss in our
 189 gravitational theories.

190 we got the CMB and geometry of the universe. So there's this thing called the cosmic Microwave
 191 Background (CMB). It's the universe's baby photo from when all of the hydrogen de-ionized to form
 192 atoms. This happened cause it was cold enough finally from the expansion of the universe. The
 193 recombination happened sometime around less than 1 mil years after the universe was born [FACT
 194 CHECK THIS][NEEDS A SOURCE]. when hydrogen absorbs an electron, it releases a photon of
 195 a specific wavelength. This wavelength amounts to 13 ev or so according to the qm eqn. . .

Figure 2.3 **TODO: bullet cluster photo.****[NEEDS A SOURCE]****[FACT CHECK THIS]**

INSERThydrogenenergylevelHERE. (2.2)

196

197 However the universe has been expnding since it's creation. In fact the time and space itself is
 198 exanding away from us for as long as the universe is old. This red-shifts the combination light into
 199 the Microwave frequencies. This is the light we can detect with microwave observatories and is
 200 what was first detected by so and so in the 19?? **[NEEDS A SOURCE]****[FACT CHECK THIS]**This
 201 make a microwave image seen below after we subtract the average of the image.

202 We can do a funny thing with the photo but it's fairly straight forward. Shove the photo into a
 203 spherical harmonic decomposition. This gives you the vibrational modes of the CMB and therefore
 204 the early universe. The important thing to note is that the harmoincs are based on primordial
 205 baryonic acoustic oscillations **[FACT CHECK THIS]**This is directly linked with the energy density

Figure 2.4 **TODO: CMB photo****[NEEDS A SOURCE]****[FACT CHECK THIS]**

206 of the universe and how these couple. It's a cosmology and geometry thing.

207 The harmonics would look very different for a universe with less dmm (see fig bla) or a lot more
208 dm (see fig bla)

209 The observations fit well with the Lambda CDM model and we derive the primordial dm
210 concentration to be XX% and primordial DM to be XX%. **TODO: What are the shortcomings?**
211 think the most obvious argument is simply that this is very old light, up to 13.6 billion years old.
212 It's not at all necessary that the universe shares the exact same DM, matter ratio. There is a poorness
213 in fit in the lower region of the graph and this is unexplained. The way we measure distance can be
214 really fucked sometimes so maybe that's a problem too.

215 Finally we have universe simulations like the millenium simultation and more **[FACT CHECK**
216 **THIS]****[NEEDS A SOURCE]**. These are computer simulations of the universe with different fractions
217 of DM and baryonic matters. Additionaly hypotheses are tested like how hot the DM is and how

Figure 2.5 TODO: Plan harmonics of CMB[NEEDS A SOURCE][FACT CHECK THIS]

218 strongly it interacts with itself and with baryonic matter. These simulations are also done for smaller
 219 scales like galactic formation and galaxy clustering. In all cases the simulations most resemble
 220 out universe for a Lambda CDM like universe.

221 The main issues with the simulations is mostly that we cant perfectly simulate the universe.
 222 They are often incomplete with how they treat baryonic matter and make big assumptions about
 223 dark matter. These simulations also have to contend with very real computational limitations. The
 224 resolution of some of the universe simulations are as large at XX's of solar masses. There's reason
 225 to beleive that the resolution might really matter as well. [NEEDS A SOURCE][FACT CHECK
 226 THIS]

227 Overall this forms a compelling arguement for dark matter. However, these observations really
 228 only confirm that DM is there. It takes another leap of theory to make observations of DM that
 229 are nongravitational. One of which is the emergence of the Weakly Interacting Massive Particle

Figure 2.6 **TODO: Plank harmonics vs DM content CMB[NEEDS A SOURCE][FACT CHECK THIS]**

230 hypothesis of DM. This DM candidate theory is discussed further in the next section.

231 **2.4 Searching for Dark Matter**

232 We've explored any options for what dark matter could be now. The remainder of this thesis
 233 I will focus only on a particle dark matter hypothesis. I will not be discussing alternative gravita-
 234 tional theories such as Modified Newtonian Dynamics. I am also ignoring composite dark matter
 235 discussion like primordial black holes, dark atoms, or dark bound states of baryonic matter. For
 236 this thesis I focus on the hypothesis that DM is a weakly interacting and massive particle (WIMP).

237 The current status of the standard model does not have a WIMP candidate. When looking at
 238 the standard model, we can immediately exclude any charged particle. This is because charged
 239 particles interact with light and so much DM would be immediately visible if it had the same
 240 charge as SM particles. Specifically this will rule out the following charged, fundamental particles:
 241 $e, \mu, \tau, W, u, d, s, c, t, b$ and their corresponding antiparticles. Recalling from earlier that DM must

Figure 2.7 **TODO: Standard model. Square or Circle?**[NEEDS A SOURCE][FACT CHECK THIS]

be long lived and stable over the age of the universe. This would exclude all SM particles with decay half-lives at or shorter than the age of the universe. This constraint eliminates the Z , and H bosons. Finally, the candidate DM needs to be somewhat massive. This follows from the DM needing to be cold or not relativistic through the universe. This eliminates the remaining SM particles: $\nu_e, \mu, \tau, g, \gamma$. This indicates the SM that is likely not the full story and hints to physics beyond the standard model (BSM).

2.4.1 Shake it, Break it, Make it

The above figure demonstrates the different interaction modes possible with particle DM and the DM. The figure is a simplified Feynman diagram where the arrow of time represents the interaction modes of: **Shake it, Break it, Make it**.

Shake it refers to the direct detection of dark matter. Direct detection interactions start with a free DM particle and some SM particle. The DM and SM interact under some elastic or inelastic

Figure 2.8 **TODO: Shake it, break it, make it**[NEEDS A SOURCE][FACT CHECK THIS]

collision and recoil away from each other. The DM remains in the dark sector and imparts some momentum onto the SM particle. The hope is that the momentum imparted onto the SM particle is sufficiently high enough to ick up with highly sensitive instruments. Because we cannot create the DM in the lab, we have to wait until it is incident on the detector. We do this by increasing the interaction volume of the detector with some inert chemical. We then leverage the hypothesis that the DM is everywhere around us and Earth's motion through the cosmos creates a sort of DM wind. Direct detectors are live now and taking data. Some active experiments include XENON **TODO: look up and name direct DM experiments.**

Make it refers to the production of DM from SM initial states. The experiment starts with particles in the SM. These SM particles are accelerated to incredibly high energies and then collided with each other. In the confluence of energy DM emerges as a byproduct of the SM annihilation. Often it is the collider experiments that are able to generate energies high enough to probe DM.

Figure 2.9 **TODO: windy dark matter. Look at Jodi's DM lectures[NEEDS A SOURCE][FACT CHECK THIS]**

These experiments include the renowned ATLAS and CMS collaborations at CERN where protons are collided together at extreme energies. The DM searches however are complex. DM likely does not interact with the detectors and lives long enough to escape the detection apparatus of CERN's colliders. This means any DM search with production searches for an excess of events with missing energy in the events. The missing energy with no particle tracks implies a neutral particle carried the energy out of the detector. However, there are other neutral particles in the SM and so any analysis have to discriminate between SM signatures of missing energy and a potential DM candidate.

2.4.2 Break it: Standard Model Signatures of Indirect Dark Matter Searches

Break it refers to the creation of SM particles from the dark sector, and it is the primary concern of this thesis. The interaction begins with dark matter or in the dark sector. The hypothesis is that this DM will either annihilate with itself or decay and produce a SM byproduct which we can detect. This method is often referred to the Indirect detection of DM because we have no lab to directly

Figure 2.10 **TODO: A particle event in CMS/ATLAS with Missing E****[NEEDS A SOURCE]****[FACT CHECK THIS]**

278 control or manipulate the DM. Therefore most DM primary observations will be performed from
 279 observations of known DM densities among the cosmos. The strength is that we have the entirety
 280 of the universe and its lifespan to use as the detector or particle accelerator. Additionally, locations
 281 of dark matter are also well understood since it was astrophysical observations that presented the
 282 problem of DM in the first place.

283 However, anything can happen in the universe. So there are many difficult to deconvolve
 284 backgrounds when searching for a DM signal. One prominent example is the galactic center.
 285 There's a lot of DM there since the Milky Way definitely has a lot of DM. But any signal coming
 286 from there is hard to parse apart from the extreme environment of our supermassive black hole,
 287 Sagittarius A* In fact, there has been known γ -ray excesses from the galactic center **[NEEDS A**
 288 **SOURCE]**, yet the environment presents a difficult problem in sussing out what the fuck is actually
 289 going on. Despite the challenges, any DM model that yields evidence in the other observation

290 two methods, **Shake it or Make it** must be corroborated with indirect observations of the known
291 DM overdensities. Without corroborating Evidence, DM observation in the lab is hard pressed to
292 demonstrate that it is the model contributing to the DM seen at the universal scale.

293 In the case of WIMP DM, signals are typically described in terms of primary SM particles
294 produced from a DM decay or annihilation. These particles are then simulated to stable final states
295 such as: γ , ν , p , or e which can traverse galactic lengths to reach the earth.

Figure 2.11 **TODO: particle cascade from DM[NEEDS A SOURCE][FACT CHECK THIS]**

296 The figure shows the quagmire of SM particles that emerges from SM initial states that are not
297 stable. There's a lot of different things with different energies that can pop out.

298 For any neutral messenger, the DM flux from DM annihilating to some particle in the SM, φ ,
299 from a region in the sky is

$$\text{INSERTDMannfluxequationHERE.} \quad (2.3)$$

300

301 **TODO: explain the equation** And for decay it is . . .

$$\textcolor{green}{INSERT DM decay flux eq HERE.} \quad (2.4)$$

302

303 **TODO: explain the equation**

304 The integral over a line of sight is a simplification made because we mostly observe a 2d
305 surface with our Astrophysics experiments. This also translates the equation into observables in
306 our detector like solid angle. The spectral shape is mostly determined by the SM primary products.
307 From HDMSpectra, they look like the following figures for the bb, tau, and Z spectra.

Figure 2.12 **TODO: HDMSpectra: bb, tautau, WW[NEEDS A SOURCE][FACT CHECK THIS]**

308 Additionally, when DM primarily goes into one of the neutral messengers (nu or gamma), the
309 spectra will typically have a line feature. These messengers are very unlikely to be attenuated in

any way from their primary state. These line spectra are usually considered smoking gun signals as their energy will be half the COM of the DM \rightarrow SM process. For DM in the GeV+ scale, there is no similar SM process and so seeing the signal would almost certainly be an indication of the presence of dark matter.

Figure 2.13 **TODO: Line spectra, nu and gamma[NEEDS A SOURCE][FACT CHECK THIS]**

We fortunately have the largest volume and lifetime ever for a particle physics experiment in the universe. This means we can do some pretty cool shit very efficiently. The drawn back are the backgrounds.

2.5 Multi-Messenger Dark Matter

Astrophysics entered a dope as fuck new phase in the past few decades that leverages our new knowledge of the SM and general relativity. Up until the 21st century, astrophysical observations were done with photons. At first, observations were optical in nature. You can confirm this yourself by going outside at night. The moon and constellations are observabke to the naked eye. In darker

places on Earth, celestial bodies like our Milky Way galaxy become visible. Novel observations of the universe have since only adjusted the sensitivity of the wavelength of light that's observed. Gems like the CMB, MEERkat, [NEEDS A SOURCE] and more have ultimately been observations of different wavelengths of light. Light can also be thought of as a particle in the SM is referred to as a photon, or a packet of light.

Figure 2.14 TODO: multimessenger sectors from the NSF[NEEDS A SOURCE][FACT CHECK THIS]

Come the 21st century and we've started to use more of the SM and general relativity. The experiments LIGO and VIRGO had an iconic discovery in 2015??[FACT CHECK THIS] with the first chirps of black hole mergers. This opened an entirely new method of observing the universe through gravitational waves. They literally use the bending of space-time to do astrophysics like holy shit. There's also been a surge of interest in the neutrino sector. We're now finally having some sensitivity to neutrinos that we're able to detect them from astrophysical sources. Neutrinos, like gravitational waves and light, travels mostly unimpeded from their source to our observatories.

334 This makes pointing to the originating source of these messengers much easier than it is for
335 cosmic rays that are almost always deflected from their source.

Figure 2.15 **TODO: Milky way at different wavelengths****[NEEDS A SOURCE]****[FACT CHECK THIS]**

336 Being able to see the same objects under different regimes was demonstrated already with just
337 photons. From the previous figure you can see different ways to look at the milky way galaxy. Each
338 panel corresponds to a different wavelength of light which has different penetrations through gas
339 and galactic dust. Some sources are more apparent in some panels, while others are not. Recently,
340 the IceCube collaboration published a groundbreaking result of the milky way in neutrinos. This
341 new channel is very unique because we can really see through the galaxy. This new image also
342 refines our understanding of how high energy particles are accelerated since the fit to IceCube data
343 prefers one standard model process over the other.

344 Exposing our observations to more cosmic messengers greatly increases our sensitivity to rare
345 processes. In the case of DM, from fig (SM ann), you can see there are many SM particles at the end

346 of the particle cascade. Among the final states are gammas and neutrinos. The charged particles
347 however would not likely make it to earth since they'll be deflected. This means observatories that
348 can see the neutral messengers are especially good for DM searches and for combining data for a
349 multi-messenger search.

350 **2.6 Search Targets for Dark Matter**

351 We of course have to know where to look. Thankfully, we have a good idea of where. Our
352 first detection of DM relied on optical observations. Since then, we've developed new techniques
353 to find large DM dense regions. We first found out about DM through observing galactic rotation
354 curves. This includes our nearest galaxy, the Milky Way. The Milky Way thus is the largest nearby
355 DM dense region to look at. Additionally, the DM halo surrounding the Milky Way is somewhat
356 clumpy [NEEDS A SOURCE]. There are regions in the DM halo of the Milky Way that have more
357 DM than others and it's captured gas over time. In some cases these sub-haloes were dense enough
358 to create stars. These apparent sub galaxies are known as dwarf spheroidal galaxies and are the
359 main sources studied in this thesis.

360 **2.6.1 Dwarf Spheroidal Galaxies**

361 The way we look for dwarf spheroidal galaxies (dSph's) is through mostly Newtonian physics.
362 We use either the virial theorem to determine the DM density of the dSph's or a Jeans analysis /ns.
363 DSphs tend to be ideal sources to look at for DM searches. The reason is that these environments
364 are fairly quiet. Unlike the galactic center, the most active components of dSph's are the stars within
365 them. There are few compact objects, like black holes, and much less gas that would contribute
366 to a large background. The DM to mass ratio here is also massive. [NEEDS A SOURCE]. The
367 signal to background ratio is really large and we expect a lot of signal from how much dark matter
368 there is. All this together means that dSph's are among the best sources to look at for indirect DM
369 searches.

CHAPTER 3

370 **DETECTING HIGH ENERGY NEUTRAL MESSENGERS**

371 **3.1 Cherenkov Radiation**

372 **3.2 HAWC**

373 **3.3 IceCube**

374 **3.4 Opportunities to Combine for Dark Matter**

CHAPTER 4

375 HIGH ALTITUDE WATER CHERENKOV (HAWC) OBSERVATORY

376 4.1 The Detector

377 4.2 Events Reconstruction and Data Acquisition

378 4.2.1 G/H Discrimination

379 4.2.2 Angle

380 4.2.3 Energy

381 4.3 Remote Monitoring

382 4.3.1 ATHENA Database

383 4.3.2 HOMER

CHAPTER 5

384

ICECUBE NEUTRINO OBSERVATORY

385 5.1 The Detector

386 5.2 Events Reconstruction and Data Acquisition

387 5.2.1 Angle

388 5.2.2 Energy

389 5.3 Northern Test Site

390 5.3.1 Pigeon remote dark rate testing

391 5.3.2 Bulkhead Construction

CHAPTER 6

392 **COMPUTATIONAL TECHNIQUES IN PARTICLE ASTROPHYSICS**

393 **6.1 Neural Networks for Gamma/Hadron Separation**

394 **6.2 Parallel Computing for Dark Matter Analyses**

CHAPTER 7

395

GLORY DUCK

CHAPTER 8
