CHAPTER 2

DARK MATTER IN THE COSMOS

2.1 Introduction

I'll attempt to explain the dark matter problem at an entry level with the following thought experiment. Let's say you're the teacher for an elementary school classroom. You take them on a field trip to your local science museum and among exhibits is one for mass and weight. You see the gigantic scale and come up with a fun problem.

You say to your class, "What is the weight of the classroom? Give me your guess to me in 30 minutes and then we'll check on the scale. If your guess is within 10% of the right answer, we will have a movie day tomorrow with a movie of your choice."

The kids are ecstatic to hear this, and they get to work. The solution is straight forward. The students should give each other their weight or best guess if they don't know. Then all they have to do is add each student's weight and get a grand total for the class. The measurement on the giant scale should show the true weight of the class. When comparing the measured weight, multiply the observation by 1.1 and 0.9 in order to get the $\pm 10\%$ tolerance respectively.

Two of your students, Sandra and Mario, return to you with a solution.

They say, "We weren't sure of everyone's weight. We used 65 lbs for the people we didn't know and added everyone who does know. There's 30 of us, and we got 2000 lbs! That's a ton!"

You estimated 1900 lbs assuming the average weight of a student in your class was ~60 lbs. So you're pleased with this answer. You instruct your students to all gather on the giant scale and read off the weight together. To all of your surprise, the scale reads *10 thousand lbs!* This is way more than a 10% error. In fact this is 5 times more massive than either your or your students' estimates. You think to yourself and conclude there must be something wrong with the scale. You ask an employee to check the scale and verify it is calibrated well. They confirm that the scale is in fact in working order. You then weigh a couple students individually, maybe the scale is not properly calibrated. Alice weighs 59 lbs, and Bob weighs 62 lbs, typical weights for their age. You then weigh each student individually and see that their weights individually do not deviate greatly from

60 lbs. So where does all the extra weight come from?

This is in essence the Dark Matter problem. The important substitution to make however is to replace the students with stars and classroom with a galaxy, say the Milky Way. Individually the mass of stars is well measured and defined with the Sun as our nearest test case. However, when we set out to measure a collection of stars as large as galaxies, our well motivated estimation is wildly incorrect. There simply is no way to account for this discrepancy except without some unseen, or dark, contribution to mass and matter in galaxies. I set out in my thesis to narrow the possibilities of what this Dark Matter can be.

This chapter is organized like the following. . . **TODO: Text should look like ... Chapter x has blah blah blah.**

2.2 Dark Matter Basics

Dark Matter (DM) has been a whispering problem in physics for almost 100 years. Anomalies have been detected by way of weird galaxy behaviour, budding Cosmology, and more **[NEEDS A SOURCE]**. It was sometime in 1930's when the super duper smart Zwicky measured that it was definitely there. It's kind of a big deal because we have no idea what the nature of this stuff and there's a lot of it. According to Lambda CDM, the most legit model, **[NEEDS A SOURCE]** DM is about 85% **[FACT CHECK THIS]**, of all mass in the universe. It's called dark in fact because we cannot see it. **[NEEDS A SOURCE]** Finding out what the hell it is, is an active field of research and hopefully it interacts with the standard model.

Here's what we do know about DM so far. . . DM is dark, it doesn't interact readily with light. DM also doesn't interact noticeably with the other standard model forces (EM, Strong, Weak) at a rate that matters **[NEEDS A SOURCE]**. DM is cold. By cold I mean that it is most likely not moving at relativistic speeds like neutrinos and photons. **[NEEDS A SOURCE]** If it was moving that fast, the structures we see like galaxies would be much more diffuse than what is observed. **[NEEDS A SOURCE]** DM is old. DM played a critical role in the formation of the universe and the structure within it. **[NEEDS A SOURCE]** We know this from Cosmology and computer universe simulations **[NEEDS A SOURCE]**.

The search for DM is basically summarized by trying a bunch of different models and performing measurements of all kinds to test them. These models of course have to nominally agree with the known observations seen over the last century. Whenever we perform a test and don't see anything, the parameter spaces gets more constrained. I discuss some of the ideas and approaches further on. I Especially discuss the models that are relevant to my thesis.

We fortunately have the largest volume and lifetime ever for a particle physics experiment in the universe. This means we can do some pretty cool shit very efficiently. The drawn back are the backgrounds.

2.3 Evidence for Dark Matter

Let me show you why we're pretty sure DM is a thing and why it might be particle like in nature. My thesis focuses on WIMP dark matter which is one of the better motivated things out there There were some weird as fuck anomalies early in the last century but we weren't 100% that it was legit. Then some great scientists made some keen measurements of stars and their minds were blown. Read more to see what we know now. I promise you're about to get mind fucked.

2.3.1 First Clues: Stellar Velocities

Ok so someone [FACT CHECK THIS][NEEDS A SOURCE] started taking measurements with at. They were curious about what speed stars were orbiting the galaxies they were contained in. These measurements were done for things close by. At the time we were even that sure galaxies were a thing. But with the basic knowledge we had we used the virial theorem with the velocities of the stars to measure the mass indirectly of the galaxies.

$$\text{INSERT The Virial Eqn HERE.} \quad (2.1)$$

TODO: explain the virial equation[NEEDS A SOURCE] you probably want to source the theory behind why this important

The verdict wasn't clear however until Vera Rubin made some awesome discoveries with more precise equipment and 21cm lines of Hydrogen gas in the galaxies. This really showed that

there was some unexplained discrepancy between how much mass we were seeing in the stars and the mass measured indirectly. The issue is that it we're pretty sure now that we're not just under-estimating the mass of the stars [NEEDS A SOURCE]. The difference in mass was up to 5x which is way way too much for what our uncertainties were (somewhere around 20%)[NEEDS A SOURCE].

Figure 2.1 TODO: velocity dispersion old here.[NEEDS A SOURCE][FACT CHECK THIS]

Nowadays we have more measurements of the stellar velocities and have even discovered small DM dense bodies called dwarf spheroidals (dSph) These measurements have been made by the community [FACT CHECK THIS]and there are compiled lists of how much DM these objects have. Most of these measurements are made from newtonian virial theorem measurments. There has since emerged new evidence. These innovative techs are discussed in the following sections. The evidence cullminates into a story of particle dark matter.

2.3.2 Mounting Evidence for Dark Matter

Modern evidence for dark matter comes from new avenues. We got microlensing which supports DM in the general relativity sector. The Cosmic Microwave Background shows that the universe has DM in it from a very early stage. The CMB is the primordial light from the young universe. Basically a baby photo. Then we have computational models where we model the universe. Then we look at how the simulated universes look like compared to what we see. From those simulations we infer how much dark matter is in the universe. The fuller explanations and shortcoming of each of these methods is explained further in this section.

someone took a an observation of the bullet cluster. The microlensing of galaxy clusters are some of the most damning evidence that DM is actually matter and not just a flaw in our gravitational theories. There were two galaxy clusters [FACT CHECK THIS]. They clearly passed through each other at some point in the past and are in the process of merging [NEEDS A SOURCE]. Two observations of the clusters were made independantly of each other. The first was the microlensing of light around the galaxies due to their gravitational influences. When celestial bodies are large enough, the gravity they exert bends space and time itself. This bending effects light and will deflect light in a smilar way to how lenses will bend light.

With a sufficient understanding of light sources behind a celestial body, you can reconstruct the countours of the gravitational lenses. The gradient of the contours then tells you how dense the matter is and where it is.

They then made measurements of the x-ray emmision from the clusters. The idea is that since these galaxies are mostly gass and are merging, then they should be getting hotter. If they're merging, the x-ray emmisions should be the strongest where the gas is mostly moving through each other. The x-rays basically map out where the gas is in these merging galaxies.

The dope super interesting thing is that the map of the x-ray emmisions totally doesnt align with the gravitational countours from the microlensing. This incongruence is really telling that there is a lot of matter somewhere that we jsut cannot see. Moreover this matter is NOT BARYONIC. So then what is it? This measurement didn't really tell us what exactly, but it did suggest that this DM

Figure 2.2 **TODO: gravitational lensing figure compared to glass lensing.**[NEEDS A SOURCE][FACT CHECK THIS]

also doesn't interact with itself very strongly. If it did, then it would have been more aligned with where the x-ray emission was. There's been other studies of galaxies with similar results although there are a handful that resemble something we expect for strongly self-interacting DM. [NEEDS A SOURCE]. This result really makes it hard to argue that DM is somehow something amiss in our gravitational theories.

we got the CMB and geometry of the universe. So there's this thing called the cosmic Microwave Background (CMB). It's the universe's baby photo from when all of the hydrogen de-ionized to form atoms. This happened because it was cold enough finally from the expansion of the universe. The recombination happened sometime around less than 1 million years after the universe was born [FACT CHECK THIS][NEEDS A SOURCE]. When hydrogen absorbs an electron, it releases a photon of a specific wavelength. This wavelength amounts to 13 eV or so according to the QM eqn. . .

Figure 2.3 **TODO: bullet cluster photo.**[NEEDS A SOURCE][FACT CHECK THIS]

INSERThydrogenenergylevelHERE. (2.2)

However the universe has been expnding since it's creation. In fact the time and space itself is exanding away from us for as long as the universe is old. This red-shifts the combination light into the Microwave frequencies. This is the light we can detect with microwave observatories and is what was first detected by so and so in the 19?? [NEEDS A SOURCE][FACT CHECK THIS]This make a microwave image seen below after we subtract the average of the image.

We can do a funny thing with the photo but it's fairly straight forward. Shove the photo into a spherical harmonic decomposition. This gives you the vibrational modes of the CMB and therefore the early universe. The important thing to note is that the harmoincs are based on primordial baryonic acoustic oscillations [FACT CHECK THIS]This is directly linked with the energy density

Figure 2.4 **TODO: CMB photo****[NEEDS A SOURCE]****[FACT CHECK THIS]**

of the universe and how these couple. It's a cosmology and geometry thing.

The harmonics would look very different for a universe with less dmm (see fig bla) or a lot more dm (see fig bla)

The observations fit well with the Lambda CDM model and we derive the primordial dm concentration to be XX% and primordial DM to be XX%. **TODO: What are the shortcomings?** I think the most obvious argument is simply that this is very old light, up to 13.6 billion years old. It's not at all necessary that the universe shares the exact same DM, matter ratio. There is a poorness in fit in the lower region of the graph and this is unexplained. The way we measure distance can be really fucked sometimes so maybe that's a problem too.

Finally we have universe simulations like the millenium simulation and more **[FACT CHECK THIS]****[NEEDS A SOURCE]**. These are computer simulations of the universe with different fractions of DM and baryonic matters. Additionally hypotheses are tested like how hot the DM is and how

Figure 2.5 **TODO: Plan harmonics of CMB****[NEEDS A SOURCE]****[FACT CHECK THIS]**

strongly it interacts with itself and with baryonic matter. These simulations are also done for smaller scales like galactic formation and galaxy clustering. In all cases the simulations most resemble out universe for a Lambda CDM like universe.

The main issues with the simulations is mostly that we cant perfectly simulate the unverse. They are often incomplete with how they treat baryonic matter and make big assumptions about dark matter. These simulations also have to contend with very real computational limitations. The resulation of some of the universe simulations are as large at XX's of solar masses. There's reason to beleive that the resulation might really matter as well. **[NEEDS A SOURCE]****[FACT CHECK THIS]**

Overall this forms a compelling arguement for dark matter. However, these observations really only confirm that DM is there. It takes another leap of theory to make observations of DM that are nongravitational. One of which is the emergence of the Weakly Interacting Massive Particle

Figure 2.6 **TODO: Plank harmonics vs DM content CMB[NEEDS A SOURCE][FACT CHECK THIS]**

hypothesis of DM. This DM candidate theory is discussed further in the next section.

2.4 Searching for Dark Matter

We've explored any options for what dark matter could be now. The remainder of this thesis I will focus only on a particle dark matter hypothesis. I will not be discussing alternative gravitational theories such as Modified Newtonian Dynamics. I am also ignoring composite dark matter discussion like primordial black holes, dark atoms, or dark bound states of baryonic matter. For this thesis I focus on the hypothesis that DM is a weakly interacting and massive particle (WIMP).

The current status of the standard model does not have a WIMP candidate. When looking at the standard model, we can immediately exclude any charged particle. This is because charged particles interact with light and so much DM would be immediately visible if it had the same charge as SM particles. Specifically this will rule out the following charged, fundamental particles: $e, \mu, \tau, W, u, d, s, c, t, b$ and their corresponding antiparticles. Recalling from earlier that DM must

Figure 2.7 **TODO: Standard model. Square or Circle?****[NEEDS A SOURCE]****[FACT CHECK THIS]**

be long lived and stable over the age of the universe. This would exclude all SM particles with decay half-lives at or shorter than the age of the universe. This constraint eliminates the Z , and H bosons. Finally, the candidate DM needs to be somewhat massive. This follows from the DM needing to be cold or not relativistic through the universe. This eliminates the remaining SM particles: $\nu_{e,\mu,\tau}, g, \gamma$. This indicates the SM that is likely not the full story and hints to physics beyond the standard model (BSM).

2.4.1 Shake it, Break it, Make it

The above figure demonstrates the different interaction modes possible with particle DM and the DM. The figure is a simplified Feynman diagram where the arrow of time represents the interaction modes of: **Shake it, Break it, Make it**.

Shake it refers to the direct detection of dark matter. Direct detection interactions start with a free DM particle and some SM particle. The DM and SM interact under some elastic or inelastic

Figure 2.8 **TODO: Shake it, break it, make it**[NEEDS A SOURCE][FACT CHECK THIS]

collision and recoil away from each other. The DM remains in the dark sector and imparts some momentum onto the SM particle. The hope is that the momentum imparted onto the SM particle is sufficiently high enough to ick up with highly sensitive instruments. Because we cannot create the DM in the lab, we have to wait until it is incident on the detector. We do this by increasing the interaction volume of the detector with some inert chemical. We then leverage the hypothesis that the DM is everywhere around us and Earth's motion through the cosmos creates a sort of DM wind. Direct detectors are live now and taking data. Some active experiments include XENON **TODO: look up and name direct DM experiments.**

Make it refers to the production of DM from SM initial states. The experiment starts with particles in the SM. These SM particles are accelerated to incredibly high energies and then collided with each other. In the confluence of energy DM emerges as a byproduct of the SM annihilation. Often it is the collider experiments that are able to generate energies high enough to probe DM.

Figure 2.9 **TODO: windy dark matter. Look at Jodi's DM lectures[NEEDS A SOURCE][FACT CHECK THIS]**

These experiments include the renowned ATLAS and CMS collaborations at CERN where protons are collided together at extreme energies. The DM searches however are complex. DM likely does not interact with the detectors and lives long enough to escape the detection apparatus of CERN's colliders. This means any DM search with production searches for an excess of events with missing energy in the events. The missing energy with no particle tracks implies a neutral particle carried the energy out of the detector. However, there are other neutral particles in the SM and so any analysis have to discriminate between SM signatures of missing energy and a potential DM candidate.

2.4.2 Break it: Standard Model Signatures of Indirect Dark Matter Searches

Break it refers to the creation of SM particles from the dark sector, and it is the primary concern of this thesis. The interaction begins with dark matter or in the dark sector. The hypothesis is that this DM will either annihilate with itself or decay and produce a SM byproduct which we can detect. This method is often referred to the Indirect detection of DM because we have no lab to directly

Figure 2.10 **TODO: A particle event in CMS/ATLAS with Missing E**[\[NEEDS A SOURCE\]](#)[\[FACT CHECK THIS\]](#)

control or manipulate the DM. Therefore most DM primary observations will be performed from observations of known DM densities among the cosmos. The strength is that we have the entirety of the universe and its lifespan to use as the detector or particle accelerator. Additionally, locations of dark matter are also well understood since it was astrophysical observations that presented the problem of DM in the first place.

However, anything can happen in the universe. So there are many difficult to deconvolve backgrounds when searching for a DM signal. One prominent example is the galactic center. There's a lot of DM there since the Milky Way definitely has a lot of DM. But any signal coming from there is hard to parse apart from the extreme environment of our supermassive black hole, Sagittarius A*. In fact, there have been known γ -ray excesses from the galactic center [\[NEEDS A SOURCE\]](#), yet the environment presents a difficult problem in sussing out what the fuck is actually going on. Despite the challenges, any DM model that yields evidence in the other observation

two methods, **Shake it or Make it** must be corroborated with indirect observations of the known DM overdensities. Without corroborating Evidence, DM observation in the lab is hard pressed to demonstrate that it is the model contributing to the DM seen at the universal scale.

In the case of WIMP DM, signals are typically described in terms of primary SM particles produced from a DM decay or annihilation. These particles are then simulated to stable final states such as: γ , ν , p , or e which can traverse galactic lengths to reach the earth.

Figure 2.11 **TODO: particle cascade from DM[NEEDS A SOURCE][FACT CHECK THIS]**

The figure shows the quagmire of SM particles that emerges from SM initial states that are not stable. There's a lot of different things with different energies that can pop out.

For any neutral messenger, the DM flux from DM annihilating to some particle in the SM, φ , from a region in the sky is

$$\text{INSERT DM ann flux equation HERE.} \quad (2.3)$$

TODO: explain the equation And for decay it is . . .

$$INSERT DM decay flux eq HERE. \quad (2.4)$$

TODO: explain the equation

The integral over a line of sight is a simplification made because we mostly observe a 2d surface with our Astrophysics experiments. This also translates the equation into observables in our detector like solid angle. The spectral shape is mostly determined by the SM primary products. From HDMSpectra, they look like the following figures for the bb, tau, and Z spectra.

Figure 2.12 TODO: HDMSpectra: bb, tautau, WW[NEEDS A SOURCE][FACT CHECK THIS]

Additionally, when DM primarily goes into one of the neutral messengers (nu or gamma), the spectra will typically have a line feature. These messengers are very unlikely to be attenuated in

any way from their primary state. These line spectra are usually considered smoking gun signals as their energy will be half the COM of the DM \rightarrow SM process. For DM in the GeV+ scale, there is no similar SM process and so seeing the signal would almost certainly be an indication of the presence of dark matter.

Figure 2.13 TODO: Line spectra, nu and gamma[NEEDS A SOURCE][FACT CHECK THIS]

2.5 Multi-Messenger Dark Matter

Astrophysics entered a dope as fuck new phase in the past few decades that leverages our new knowledge of the SM and general relativity. Up until the 21st century, astrophysical observations were done with photons. At first, observations were optical in nature. You can confirm this yourself by going outside at night. The moon and constellations are observable to the naked eye. In darker places on Earth, celestial bodies like our Milky Way galaxy become visible. Novel observations of the universe have since only adjusted the sensitivity of the wavelength of light that's observed. Gems like the CMB, MEERkat, [NEEDS A SOURCE] and more have ultimately been observations

of different wavelengths of light. Light can also be thought of as a particle in the SM is referred to as a photon, or a packet of light.

Figure 2.14 **TODO: multimessenger sectors from the NSF[NEEDS A SOURCE][FACT CHECK THIS]**

Come the 21st century and we've started to use more of the SM and general relativity. The experiments LIGO and VIRGO had an iconic discovery in 2015??[FACT CHECK THIS] with the first chirps of black hole mergers. This opened an entirely new method of observing the universe through gravitational waves. They literally use the bending of space-time to do astrophysics like holy shit. There's also been a surge of interest in the neutrino sector. We're now finally having some sensitivity to neutrinos that we're able to detect them from astrophysical sources. Neutrinos, like gravitational waves and light, travels mostly unimpeded from their source to our observatories. This makes pointing to the originating source of these messengers much easier than it is for cosmic rays that are almost always deflected from their source.

Figure 2.15 **TODO: Milky way at different wavelengths[NEEDS A SOURCE][FACT CHECK THIS]**

Being able to see the same objects under different regimes was demonstrated already with just photons. From the previous figure you can see different ways to look at the milky way galaxy. Each panel corresponds to a different wavelength of light which has different penetrations through gas and galactic dust. Some sources are more apparent in some panels, while others are not. Recently, the IceCube collaboration published a groundbreaking result of the milky way in neutrinos. This new channel is very unique because we can really see through the galaxy. This new image also refines our understanding of how high energy particles are accelerated since the fit to IceCube data prefers one standard model process over the other.

Exposing our observations to more cosmic messengers greatly increases our sensitivity to rare processes. In the case of DM, from fig (SM ann), you can see there are many SM particles at the end of the particle cascade. Among the final states are gammas and neutrinos. The charged particles however would not likely make it to earth since they'll be deflected. This means observatories that

can see the neutral messengers are especially good for DM searches and for combining data for a multi-messenger search.

2.6 Search Targets for Dark Matter

We of course have to know where to look. Thankfully, we have a good idea of where. Our first detection of DM relied on optical observations. Since then, we've developed new techniques to find large DM dense regions. We first found out about DM through observing galactic rotation curves. This includes our nearest galaxy, the Milky Way. The Milky Way thus is the largest nearby DM dense region to look at. Additionally, the DM halo surrounding the Milky Way is somewhat clumpy [NEEDS A SOURCE]. There are regions in the DM halo of the Milky Way that have more DM than others and it's captured gas over time. In some cases these sub-haloes were dense enough to create stars. These apparent sub galaxies are known as dwarf spheroidal galaxies and are the main sources studied in this thesis.

2.6.1 Dwarf Spheroidal Galaxies

The way we look for dwarf spheroidal galaxies (dSph's) is through mostly Newtonian physics. We use either the virial theorem to determine the DM density of the dSph's or a Jeans analysis /ns. DSphs tend to be ideal sources to look at for DM searches. The reason is that these environments are fairly quiet. Unlike the galactic center, the most active components of dSph's are the stars within them. There are few compact objects, like black holes, and much less gas that would contribute to a large background. The DM to mass ratio here is also massive. [NEEDS A SOURCE]. The signal to background ratio is really large and we expect a lot of signal from how much dark matter there is. All this together means that dSph's are among the best sources to look at for indirect DM searches.
